Self-taught musical cognition and integrated audio engineering: psychoacoustic and economic impacts on contemporary phonographic production

Luis Carlos Fernandes Júnior1

SUMMARY

The dematerialization of analog recording studios, driven by the advancement of Digital Audio Workstations (DAWs), has shifted the centrality of the recording industry to the figure of the multi-instrumentalist producer. This scientific article investigates how self-taught musical acquisition, based on auditory perception, optimizes the workflow of audio engineering and the structuring of arrangements. The methodology adopted consists of an analytical-deductive review that crosses the precepts of psychoacoustics, cognitive ergonomics, and the theory of informal musical learning. The study is structured around seven theoretical axes: neuroplasticity resulting from aural learning; the conversion of the piano into a control matrix through the MIDI protocol; the mathematical management of low-frequency masking; the impact of Fletcher-Munson isophonic curves on auditory fatigue; formant analysis in dense vocal arrangements; economies of scale in independent productions; and the epistemological transition from empiricism to university academic rigor.

Theoretical evidence demonstrates that empirically trained musicians develop heuristic mappings that reduce the digital processing time of signals. It is concluded that technical mastery of acoustic engineering transforms musical intuition into a measurable logistical asset in the *streaming market.*

Keywords: Musical Cognition. Psychoacoustics. Recording Industry. Informal Learning. Audio Engineering.

ABSTRACT

The dematerialization of analog recording studios, driven by the advancement of Digital Audio Workstations (DAWs), has transferred the centrality of the phonographic chain to the multi-instrumentalist producer. This scientific article investigates how autodidactic musical acquisition, based on aural perception, optimizes the audio engineering workflow and the structuring of arrangements. The methodology adopted consists of an analytical-deductive review crossing the precepts of psychoacoustics, cognitive ergonomics, and the theory of informal musical learning. The study is structured into seven theoretical axes: neuroplasticity resulting from aural learning; the conversion of the piano into a controller matrix via the MIDI protocol; the mathematical management of low-frequency masking; the impact of Fletcher-Munson equal-loudness contours on auditory fatigue; formant analysis in dense vocal arrangements; economies of scale in independent productions; and the epistemological transition from empiricism to university academic rigor. Theoretical evidence demonstrates that musicians with empirical training develop heuristic mappings that reduce the time required for digital signal processing. It is concluded that technical mastery of acoustic engineering converts musical intuition into a measurable logistical asset in the streaming market.
