Telemetry, operational efficiency and decision making in contemporary logistics

Abstract:

Contemporary logistics has become one of the main axes of business competitiveness due to the expansion of e-commerce, the pressure for shorter lead times, and the growing need for operational predictability. In management literature, authors such as Martin Christopher, Donald Bowersox, and Douglas Lambert treat logistics as an integrated function linked to the overall performance of the supply chain. In this scenario, telemetry has come to occupy a strategic position, allowing for the monitoring of activities, routes, consumption, operational events, and execution behavior with a greater degree of granularity. This article discusses the role of telemetry in operational efficiency and logistics decision-making, focusing on its contribution to control, standardization, deviation identification, and continuous improvement. The analysis is based on real-world references from the areas of operations, logistics, and management, without the use of invented data or unverifiable claims. It starts from the premise that telemetry only produces value when integrated into a governance structure capable of transforming data into managerial action.

Keywords: logistics; telemetry; operational efficiency; governance; decision making.

In management literature, authors such as Martin Christopher, Donald Bowersox, and Douglas Lambert describe logistics as a function integrated with the overall performance of the supply chain. In this context, telemetry has gained strategic importance by enabling the monitoring of assets, routes, consumption, operational events, and execution behavior with a higher degree of detail. This article discusses the role of telemetry in operational efficiency and logistics decision-making, focusing on its contribution to control, standardization, deviation detection, and continuous improvement. The analysis is based on real references from the fields of operations, logistics, and management, without invented data or unverifiable claims. It assumes that telemetry only creates consistent value when integrated into a governance structure capable of transforming data into managerial action.

Discussion

1. Contemporary logistics as a field of progress

Modern logistics operates in an environment of increasing complexity. The multiplication of channels
sales, demand fragmentation, and the requirement for higher service levels impose
pressure on distribution networks. This scenario requires fine-tuned coordination between transportation,
Inventory, planning, customer service, and information systems.

Christopher and Lambert treat the supply chain as an interdependent system, in

It almost always involves alignment between decisions.

Telemetry contributes precisely to this cooperation because it increases visibility over the

2. Operational visibility and managerial control

The literature on management control systems shows that measurement is a necessary condition, but
not enough to manage. Kaplan and Norton emphasize that the indicators must be
linked to goals and strategy. In the field of logistics, this means that telemetry should not
to be used not only as a tracking tool, but as a basis for analysis of
performance.

The system's error message appears when the manager is able to answer questions such as: what has changed, why? What has changed and what should be done next?

3. Telemetry, standardization and operational discipline

Consistent logistics operations depend on standards. Slack and Johnston argue that... Operational performance improves when processes are clearly defined and monitored. and adjusted. Telemetry fits into this context because it provides support to the discipline of execution.

4. Data management and organizational maturity

The efficient use of telemetry depends on organizational maturity. Companies that treat the Used solely as a monitoring tool, they tend to lose some of their potential. Organizations with an analytical culture convert this information into continuous improvement. process. This difference frequently appears in the literature on digital transformation and management. of operations.

Data-driven management requires that the company knows what to measure, why to measure it, and how to act upon it. than what was measured. This implies choosing truly useful indicators, avoiding excess of Avoid sending irrelevant information and ensure that the information reaches the decision-maker. Without this structure, technology loses momentum.

This point is consistent with studies on organizational learning and continuous improvement. Deming and Juran, in different traditions, argue that operational quality depends on... The ability to understand the causes, correct processes, and reduce variations. Telemetry, in this context, is key. In that sense, it is a support tool, not a substitute for management.

The reliability of telemetry depends on information governance. This includes quality of
