Abstract: Soybean *(Glycine max* (L.) Merrill) is of great economic importance to Brazilian agribusiness; however, weed interference is one of the main limiting factors to crop productivity. In this context, chemical management with post-emergent herbicides becomes an important tool for reducing competition for water, light, nutrients, and space. Thus, this study aimed to evaluate the efficiency of post-emergent herbicides in weed management in soybean cultivation at the Sobradinho Farm, IFTM Campus Uberlândia, in Uberlândia-MG. The experiment was conducted in a randomized block design, with six treatments and four replications. The treatments consisted of: control; glyphosate; fluazifop + fomesafen; chlorimuron + haloxyfop; glyphosate + (fluazifop + fomesafen) + chlorimuron; and glyphosate + haloxyfop. The phytosociological survey of the weed community, the percentage of weed control, phytotoxicity to the soybean crop, 100-grain weight, and grain yield were evaluated. The predominant species in the experimental area were *Alternanthera tenella, Urochloa decumbens ,* and *Commelina benghalensis.* Treatments containing glyphosate, alone or in combination, showed high weed control rates, exceeding 96% 10 days after application. Treatments with fluazifop + fomesafen showed initial symptoms of phytotoxicity, but without permanent damage to the crop. Soybean yield was significantly influenced by herbicide treatments, with the highest values observed in the treatment composed of glyphosate + (fluazifop + fomesafen) + chlorimuron.

It is concluded that post-emergence chemical management was efficient in controlling weeds in the experimental area, reducing interference from the weed community and contributing to maintaining the productive potential of the soybean crop.
Keywords: *Glycine max;* chemical management; herbicides; weeds; productivity.

Abstract: Soybean *(Glycine max* (L.) Merrill) is highly important for Brazilian agribusiness; however, weed interference is one of the main limiting factors for crop productivity. In this context, chemical management with post-emergence herbicides is an important tool for reducing competition for water, light, nutrients, and space. Therefore, this study aimed to evaluate the efficiency of post-emergence herbicides in weed management in soybean cultivation at Fazenda Sobradinho, IFTM Campus Uberlândia, Uberlândia-MG, Brazil. The experiment was conducted in a randomized block design with six treatments and four replications. The treatments consisted of: control without herbicide application; glyphosate; fluazifop + medosafen; chlorimuron + haloxyfop; glyphosate + (fluazifop + medosafen) + chlorimuron; and glyphosate + haloxyfop. The evaluated variables were the phytosociological survey of the weed community, weed control percentage, phytotoxicity to soybean plants,

Initially, the area destined for soybean cultivation was desiccated with glyphosate + 2,4-D. Two weeks after desiccation, the soybean cultivar was sown. CZ37B39I2X, adding 14 seeds per linear meter and 240 kg haÿ¹ of formulated fertilizer. 08-28-26, with a spacing between furrows of 0.5 m.

The experimental plots consisted of 4 rows of soybeans, each 5 meters long. length. The usable area of the experimental plot was comprised of the two central rows, excluding 0.5 m from the ends of each row. Between the experimental plots And between the blocks, there were 1 m borders.

At the V3 phenological stage, the weeds present were sampled with a A square inventory (1 m x 1 m) was positioned within the usable area of each plot, and the following was recorded. The number of individuals of each weed species that emerged in the area. The parameters Phytosociological characteristics of the weed community were determined as proposed by Mueller-Dombois and Ellenberg (1974).

When the crop reached the V4 phenological stage, all treatments were applied. using a backpack sprayer equipped with a CO2 cylinder and a bar with 4 nozzles. Fan-type spraying. The equipment was adjusted to spray a volume of 200 L haÿ¹. of a spray solution with an application speed equivalent to 5 km hÿ¹.

While the plant was still at the V4 phenological stage, topdressing fertilization with chloride was carried out. potassium.

Phytotoxicity analysis was performed 10 and 20 days after herbicide application. in soybean plants using the rating scale proposed by the EWRC (1964), as follows:

1 = absence of phytotoxicity symptoms.

2 = minor changes (discoloration and deformation) visible in some plants

3 = small visible changes in many plants (chlorosis and curling).

4 = severe discoloration or reasonable deformation, without necrosis.

w

5 = necrosis of some leaves, accompanied by deformation in leaves and shoots.

6 = reduction in plant size, leaf curling and necrosis.

7 = more than 80% of the leaves destroyed.

8 = extremely severe damage, leaving only small green areas on the plants.

9 = death of the plants.

Disease management was carried out with the application of Unizeb Gold fungicides (3 kg). pc/ha or 2250 g of mancozeb/ha) and Priori Top (300 mL pc/ha or 60 g of azoxystrobin/ha + 37.5 g of difenoconazole/ha), applied from the R3 phenological stage, with the first The first application was done with Unizeb Gold and the second with Priori Top.

After reaching physiological maturity, the soybean plants in the usable area were counted, uprooted, and packed into sacks for grain harvesting. The grains The mass of the samples obtained was measured to estimate grain productivity per hectare.

A sample of 100 grains from each plot was evaluated in the laboratory. Regarding wet and dry mass, the oven method at 105 °C for 24 h was used. Determining grain moisture content. The mass of 100 grains and grain yield per The hectares were corrected to 13% moisture.

The collected data were analyzed in SISVAR (Ferreira, 2011) using the *F* -test. From the Analysis of Variance, at a 5% probability level; the treatments were compared to each other by Tukey's test, also at a 5% probability level.

3. RESULTS AND DISCUSSION

The weed community present in soybean cultivation, at the phenological stage. V4 was analyzed using the phytosociological survey presented in Table 2. The three species with the highest frequency, density, and abundance values (absolute or relative) were: *Alternanthera tenella, Urochloa decumbens* and *Commelina benghalensis.*

Table 2. Number of individuals present (NQ), number of individuals (NI), frequency (F), density (D), abundance (A), relative frequency (Fr), relative density (Dr), relative abundance (Ar) and importance value index (IVI) of weed species at the V4 phenological stage of the soybean cultivar CZ37B39I2X. Sobradinho Farm, Uberlândia-MG. 2024/2025 crop season.

On the other hand, grain productivity was significantly influenced by treatments. The control group showed the lowest productivity (1502.90 kg haÿ¹), evidencing The high competitive potential of weeds when not properly managed. Interference from the infesting community reduces the availability of resources essential to crop, directly impacting productive yield (Rossi *et* al., 1996).

The treatment consisting of glyphosate + (fluazifop + fomesafen) + chlorimuron showed the highest productivity (4985.48 kg haÿ¹), differing statistically from the control. This result can be explained by the high efficiency of control observed in the evaluations. previous factors, resulting in less competition during soybean development.

Treatments with glyphosate alone, fluazifop + fomesafen, and glyphosate + haloxyfop. They also exhibited high productivity, demonstrating satisfactory efficiency in management. of weeds. The treatment with chlorimuron + haloxyfop showed productivity. intermediate, possibly due to the lower initial control observed at 10 DAA.

Overall, the results demonstrate that post-emergence chemical management was fundamental for reducing weed interference and for maintaining the The productive potential of soybean cultivation, contributing to higher agronomic yields. (Oliveira *et* al., 2019).

CONCLUSION

The weed community present in the experimental area consisted of predominantly broadleaf species, with *Alternanthera tenella being a notable example.*
