Recording logistics and harmonic architecture in large-scale phonographic projects: cognitive ergonomics and sound engineering in phonological archives.

Recording logistics and harmonic architecture in large-scale phonographic projects: cognitive ergonomics and sound engineering in hymnological collections

Luis Carlos Fernandes Júnior (Juninho Fernandes)
Holds a degree in Music from the Adventist University Center of São Paulo (UNASP). Music producer, audio engineer, and arranger.

SUMMARY

The development of phonographic matrices for hymn collections requires the implementation of strategies guided by project management and cognitive ergonomics. This article analyzes the logistical structuring of large-scale recordings (projects with more than 600 phonograms) in the contemporary Christian music industry. The methodology is based on an analytical-deductive review, which combines the principles of instrumental biomechanics with theories of digital audio processing. The study proposes seven investigative axes: studio logistics management; Cognitive Load Theory applied to chord simplification; physiological limits in continuous electric bass sessions; the use of digital routing to mitigate setup time *(ramp-up);* the psychoacoustics of masking in choral arrangements; the impact of *Loudness* Standards (LUFS) in *streaming;* and the aesthetic restructuring of vocal groups. The research incorporates data from the *International Federation of the Phonographic Industry* (IFPI) and references from authors such as Lucy Green and Bob Katz. It can be concluded that the efficiency of the recording producer lies in their ability to convert erudite arrangements into accessible performances, optimizing the project budget and ensuring the liturgical functionality of the work.

Keywords: Phonographic Logistics. Popular Harmony. Audio Engineering. Cognitive Ergonomics. Large-scale Production.

ABSTRACT

The structuring of phonographic and editorial matrices for monumental hymnological collections subverts the logistics of the traditional recording workflow, necessitating methodologies grounded in process engineering and cognitive ergonomics. This scientific article analyzes the technical structuring and execution of extremely large-scale projects (exceeding 600 phonograms) in the contemporary Christian music industry. The methodology is based on an analytical-deductive approach crossing the principles of instrumental performance biomechanics with the theories of digital signal processing in Digital Audio Workstations (DAWs). The study is stratified into seven investigative axes: critical path management in the phonographic site; cognitive load theory applied to the restructuring of chord charts for guitarists; neuromuscular limitations in electric bass recording marathons; ramp-up time mitigation via routing templates; frequency masking in dense choral arrangements; compliance with streaming loudness (LUFS) standards; and the application of agile development in the production workflow. Evidence demonstrates that the producer's technical mastery is evident in the ability to translate erudite complexity into practicable performances. It is concluded that the producer acts as a systems optimizer, ensuring the budgetary viability and sociological functionality of the final collection.
